

***I. Basic Principles***

**I-M. Hydroboration**

### General Comments on Hydroboration

**Hydroboration** of alkenes proceeds with overall anti-Markovnikov selectivity.

Sources for  $\text{BH}_3$  (diborane,  $\text{BH}_3\cdot\text{THF}$ ) or sterically more hindered boranes (**9-BBN**) add to alkenes to give intermediate organoboranes which can be oxidized with  $\text{H}_2\text{O}_2$  or hydrolyzed with aqueous acid to give alcohols and alkanes, respectively.

The regioselectivity of hydroboration is determined by electronic (polarization of the B-H bond) and steric factors. The more highly hindered the substituents on borane, the higher the regioselectivity in the addition to unsymmetrically substituted alkenes.

The mechanism for hydroboration involves a *syn*-addition across the B-H bond. In the oxidation, the organic residue migrates under retention of configuration.

Kobayashi, Y.; Nakayama, Y.; Yoshida, S., "Determination of the stereoisomers of korormicin from eight possible stereoisomers by total synthesis." *Tetrahedron Lett.* **2000**, *41*, 1465-1468. Acetaldehyde oxidizes the hydroboration product. Before coupling, the boronate is converted to the ate complex.
